Introduction to Machine Learning

Advanced Risk Minimization 0-1-Loss

Learning goals

- Derive the risk minimizer of the 0-1-loss
- Derive the optimal constant model for the 0-1-loss

0-1-LOSS

- Let us first consider a discrete classifier $h : \mathcal{X} \to \mathcal{Y}$.
- The most natural choice for L(y, h) is the 0-1-loss

$$L(y,h) = \mathbb{1}_{\{y \neq h\}} = \begin{cases} 1 & \text{if } y \neq h \\ 0 & \text{if } y = h \end{cases}$$

For the binary case (g = 2) we can express the 0-1-loss for a scoring classifier f based on the margin ν := yf

 $L(y, f) = \mathbb{1}_{\{\nu < 0\}} = \mathbb{1}_{\{yf < 0\}}.$

• Analytic properties: Not continuous, even for linear *f* the optimization problem is NP-hard and close to intractable.

0-1-LOSS: RISK MINIMIZER

By the law of total expection we can in general rewrite the risk as (this all works for the multiclass case with 0-1)

$$\mathcal{R}(f) = \mathbb{E}_{xy} [L(y, f(\mathbf{x}))] = \mathbb{E}_{x} \left[\mathbb{E}_{y|x} [L(y, f(\mathbf{x}))] \right]$$
$$= \mathbb{E}_{x} \left[\sum_{k \in \mathcal{Y}} L(k, f(\mathbf{x})) \mathbb{P}(y = k \mid \mathbf{x}) \right],$$

× × ×

with $\mathbb{P}(y = k | \mathbf{x})$ the posterior probability for class *k*. For the binary case we denote $\eta(\mathbf{x}) := \mathbb{P}(y = 1 | \mathbf{x})$ and the expression becomes

$$\mathcal{R}(f) = \mathbb{E}_{\mathbf{x}} \left[L(\mathbf{1}, \pi(\mathbf{x})) \cdot \eta(\mathbf{x}) + L(\mathbf{0}, \pi(\mathbf{x})) \cdot (\mathbf{1} - \eta(\mathbf{x})) \right].$$

0-1-LOSS: RISK MINIMIZER / 2

We compute the point-wise optimizer of the above term for the 0-1-loss (defined on a discrete classifier $h(\mathbf{x})$):

$$h^{*}(\mathbf{x}) = \arg \min_{l \in \mathcal{Y}} \sum_{k \in \mathcal{Y}} L(k, l) \cdot \mathbb{P}(y = k | \mathbf{x} = \mathbf{x})$$

=
$$\arg \min_{l \in \mathcal{Y}} \sum_{k \neq l} \mathbb{P}(y = k | \mathbf{x} = \mathbf{x})$$

=
$$\arg \min_{l \in \mathcal{Y}} 1 - \mathbb{P}(y = l | \mathbf{x} = \mathbf{x})$$

=
$$\arg \max_{l \in \mathcal{Y}} \mathbb{P}(y = l | \mathbf{x} = \mathbf{x}),$$

which corresponds to predicting the most probable class.

Note that sometimes $h^*(\mathbf{x}) = \arg \max_{l \in \mathcal{Y}} \mathbb{P}(y = l | \mathbf{x} = \mathbf{x})$ is referred to as the **Bayes optimal classifier** (without closer specification of the the loss function used).

0-1-LOSS: RISK MINIMIZER / 3

The Bayes risk for the 0-1-loss (also: Bayes error rate) is

$$\mathcal{R}^* = 1 - \mathbb{E}_x \left[\max_{l \in \mathcal{Y}} \mathbb{P}(y = l \mid \mathbf{x}) \right].$$

× × 0 × × ×

In the binary case (g = 2) we can write risk minimizer and Bayes risk as follows:

$$h^*(\mathbf{x}) \hspace{.1in} = \hspace{.1in} \left\{ egin{array}{cc} 1 & \eta(\mathbf{x}) \geq rac{1}{2} \ 0 & \eta(\mathbf{x}) < rac{1}{2} \end{array}
ight.$$

$$\mathcal{R}^* = \mathbb{E}_x \left[\min(\eta(\mathbf{x}), 1 - \eta(\mathbf{x})) \right] = 1 - \mathbb{E}_x \left[\max(\eta(\mathbf{x}), 1 - \eta(\mathbf{x})) \right].$$

0-1-LOSS: RISK MINIMIZER / 4

Example: Assume that $\mathbb{P}(y = 1) = \frac{1}{2}$ and $\mathbb{P}(x \mid y) = \begin{cases} \phi_{\mu_1,\sigma^2}(x) & \text{for } y = 0\\ \phi_{\mu_2,\sigma^2}(x) & \text{for } y = 1 \end{cases}$

The decision boundary of the Bayes optimal classifier is shown in orange and the Bayes error rate is highlighted as red area.
