Introduction to Machine Learning

Information Theory Cross-Entropy and KL

× 0 0 × × ×

Learning goals

- Know the cross-entropy
- Understand the connection between entropy, cross-entropy, and KL divergence

CROSS-ENTROPY - DISCRETE CASE

Cross-entropy measures the average amount of information required to represent an event from one distribution p using a predictive scheme based on another distribution q (assume they have the same domain \mathcal{X} as in KL).

$$H(p||q) = \sum_{x \in \mathcal{X}} p(x) \log\left(\frac{1}{q(x)}\right) = -\sum_{x \in \mathcal{X}} p(x) \log\left(q(x)\right) = -\mathbb{E}_{X \sim p}[\log(q(X))]$$

For now, we accept the formula as-is. More on the underlying intuition follows in the content on inf. theory for ML and sourcecoding.

- Entropy = Avg. amount of information if we optimally encode *p*
- Cross-Entropy = Avg. amount of information if we suboptimally encode *p* with *q*
- $DL_{KL}(p||q)$: Difference between the two
- H(p||q) sometimes also denoted as $H_q(p)$ to set it apart from KL

XX

CROSS-ENTROPY - DISCRETE CASE / 2

We can summarize this also through this identity:

$$H(p\|q) = H(p) + D_{KL}(p\|q)$$

This is because:

$$\begin{aligned} H(p) + D_{\mathcal{KL}}(p \| q) &= -\sum_{x \in \mathcal{X}} p(x) \log p(x) + \sum_{x \in \mathcal{X}} p(x) \log \frac{p(x)}{q(x)} \\ &= \sum_{x \in \mathcal{X}} p(x) (-\log p(x) + \log p(x) - \log q(x)) \\ &= -\sum_{x \in \mathcal{X}} p(x) \log q(x) = H(p \| q) \end{aligned}$$

CROSS-ENTROPY - CONTINUOUS CASE

For continuous density functions p(x) and q(x):

$$H(p||q) = \int p(x) \log\left(\frac{1}{q(x)}\right) dx = -\int p(x) \log(q(x)) dx = -\mathbb{E}_{X \sim p}[\log(q(X))] \times (Q(X))$$

- It is not symmetric.
- As for the discrete case, $H(p||q) = h(p) + D_{KL}(p||q)$ holds.
- Can now become negative, as the h(p) can be negative!

CROSS-ENTROPY EXAMPLE

Let p(x) = N(0, 1) and q(x) = LP(0, 3). We can visualize

 $H(p \| q) = H(p) + D_{KL}(p \| q)$

0 0 X X 0 X X

CROSS-ENTROPY EXAMPLE

Let p(x) = LP(0,3) and q(x) = N(0,1). We can visualize

 $H(p \| q) = H(p) + D_{KL}(p \| q)$

0 0 X X 0 X X

PROOF: MAXIMUM OF DIFFERENTIAL ENTROPY

Claim: For a given variance, the continuous distribution that maximizes differential entropy is the Gaussian.

Proof: Let g(x) be a Gaussian with mean μ and variance σ^2 and f(x) an arbitrary density function with the same variance. Since differential entropy is translation invariant, we can assume f(x) and g(x) have the same mean.

The KL divergence (which is non-negative) between f(x) and g(x) is:

$$0 \leq D_{\mathcal{K}L}(f||g) = -h(f) + H(p||q)$$

= $-h(f) - \int_{-\infty}^{\infty} f(x) \log(g(x)) dx$ (1)

× × ×

PROOF: MAXIMUM OF DIFFERENTIAL ENTROPY

The second term in (1) is,

$$\int_{-\infty}^{\infty} f(x) \log(g(x)) dx = \int_{-\infty}^{\infty} f(x) \log\left(\frac{1}{\sqrt{2\pi\sigma^2}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}\right) dx$$
$$= \int_{-\infty}^{\infty} f(x) \log\left(\frac{1}{\sqrt{2\pi\sigma^2}}\right) dx + \log(e) \int_{-\infty}^{\infty} f(x) \left(-\frac{(x-\mu)^2}{2\sigma^2}\right) dx$$
$$= -\frac{1}{2} \log\left(2\pi\sigma^2\right) - \log(e) \frac{\sigma^2}{2\sigma^2} = -\frac{1}{2} (\log\left(2\pi\sigma^2\right) + \log(e))$$
$$= -\frac{1}{2} \log\left(2\pie\sigma^2\right) = -h(g), \qquad (2)$$

0 0 X X 0 X X

where the last equality follows from the normal distribution example of the entropy chapter. Combining (1) and (2) results in

$$h(g)-h(f)\geq 0$$

with equality when f(x) = g(x) (following from the properties of Kullback-Leibler divergence).
