## **Introduction to Machine Learning**

# **Regularization Weight Decay and L2**

#### **Learning goals**

- *L*2 regularization with GD is equivalent to weight decay
- Understand how weight decay changes the optimization trajectory

#### **WEIGHT DECAY VS. L2 REGULARIZATION**

Let's optimize *L*2-regularized risk of a model  $f(\mathbf{x} \mid \theta)$ 

$$
\min_{\boldsymbol{\theta}} \mathcal{R}_{\mathsf{reg}}(\boldsymbol{\theta}) = \min_{\boldsymbol{\theta}} \mathcal{R}_{\mathsf{emp}}(\boldsymbol{\theta}) + \frac{\lambda}{2} \|\boldsymbol{\theta}\|_2^2
$$

by GD. The gradient is

$$
\nabla_{\boldsymbol{\theta}} \mathcal{R}_{\mathsf{reg}}(\boldsymbol{\theta}) = \nabla_{\boldsymbol{\theta}} \mathcal{R}_{\mathsf{emp}}(\boldsymbol{\theta}) + \lambda \boldsymbol{\theta}
$$

We iteratively update  $\theta$  by step size  $\alpha$  times the negative gradient

$$
\begin{aligned} \boldsymbol{\theta}^{[\text{new}]} &= \boldsymbol{\theta}^{[\text{old}]} - \alpha \left( \nabla_{\boldsymbol{\theta}} \mathcal{R}_{\text{emp}}(\boldsymbol{\theta}^{[\text{old}]} ) + \lambda \boldsymbol{\theta}^{[\text{old}]} \right) \\ &= \boldsymbol{\theta}^{[\text{old}]} (1 - \alpha \lambda) - \alpha \nabla_{\boldsymbol{\theta}} \mathcal{R}_{\text{emp}}(\boldsymbol{\theta}^{[\text{old}]} ) \end{aligned}
$$

We see how  $\bm{\theta}^{[old]}$  decays in magnitude – for small  $\alpha$  and  $\lambda$  – before we do the gradient step. Performing the decay directly, under this name, is a very well-known technique in DL - and simply *L*2 regularization in disguise (for GD).  $\times$   $\times$ 

#### **WEIGHT DECAY VS. L2 REGULARIZATION / 2**

In GD With WD, we slide down neg. gradients of  $\mathcal{R}_{\text{emo}}$ , but in every step, we are pulled back to origin.

X X X

#### **WEIGHT DECAY VS. L2 REGULARIZATION / 3**

How strongly we are pulled back (for fixed  $\alpha$ ) depends on  $\lambda$ :

X  $\times\overline{\times}$ 

### **CAVEAT AND OTHER OPTIMIZERS**

**Caveat**: Equivalence of weight decay and *L*2 only holds for (S)GD!

- ◆ [Hanson and Pratt 1988](https://proceedings.neurips.cc/paper_files/paper/1988/file/1c9ac0159c94d8d0cbedc973445af2da-Paper.pdf) originally define WD "decoupled" from  $\bullet$ gradient-updates  $\alpha \nabla_{\bm{\theta}} \mathcal{R}_{\mathsf{emp}}(\bm{\theta}^{\mathsf{[old]}})$  as  $\boldsymbol{\theta}^{\textsf{[new]}} = \boldsymbol{\theta}^{\textsf{[old]}}(1-\lambda') - \alpha \nabla_{\boldsymbol{\theta}} \mathcal{R}_{\textsf{emp}}(\boldsymbol{\theta}^{\textsf{[old]}})$
- This is equivalent to modern WD/*L*2 (last slide) using reparameterization  $\lambda'=\alpha\lambda$
- Consequence: if there is optimal  $\lambda'$ , then optimal L2 penalty is tightly coupled to  $\alpha$  as  $\lambda = \lambda'/\alpha$  (and vice versa)
- <sup>◆ [Loshchilov and Hutter 2019](https://arxiv.org/pdf/1711.05101) Show no equivalence of L2 and WD possible</sup> for adaptive methods like Adam (Prop. 2)
- In many cases where SGD+*L*2 works well, Adam+*L*2 underperforms due to non-equivalence with WD
- They propose a variant of Adam decoupling WD from gradient updates (AdamW), increasing performance over Adam+*L*2
